Page AJ, O’Donnell TA, Blackshaw LA. Opioid modulation of ferret vagal afferent mechanosensitivity. Am J Physiol Gastrointest Liver Physiol 294: G963–G970, 2008. First published February 7, 2008; doi:10.1152/ajpgi.00562.2007.—Despite universal use of opioids in the clinic to inhibit pain, there is relatively little known of their peripheral actions on sensory nerve endings, where in fact they may be better targeted with more widespread applications. Here we show differential effects of μ-, κ-, and δ-opioids on mechanosensitive ferret esophageal vagal afferent endings investigated in vitro. The effects of selective agonists [D-Ala2,N-Me-Phe4,Gly-ol5]-enkephalin (DAMGO), 2-(3,4-dichlorophenyl)-N-methyl-V-[(1S)-1phenyl-2-(1-pyrrolidinyl) ethyl] acetamide hydrochlorine (IC199441), and (+)-4-(25R)-4-allyl-2,5-dimethyl-1-piperazinyl)-3-methoxybenzyl]-N,N-diethylbenzamide (SNC-80), respectively, on mechanosensory stimulus-response functions were quantified. DAMGO (10−7 to 10−5 M) had no effect on responses to tension, and SNC-80 (10−5 to 10−3 M) had no effect other than a minor inhibition of mucosal receptor responses to intense stimuli at 10−3 M. We conclude that μ- and κ-opioids have potent and selective peripheral effects on esophageal vagal afferents that may have applications in treatment of disorders of visceral sensation.

vagal afferents; neuromodulation; esophagus

OPIOID RECEPTORS WERE IDENTIFIED more than 30 years ago as the primary targets with which morphine and its derivatives interact to exert their analgesic and other effects. The receptors, along with their endogenous ligands, enkephalins, endorphins, and other opioid peptides, are widely distributed in the central and peripheral nervous system and play an important role in modulating endocrine, immune, cardiovascular, and gastrointestinal functions. Three major types of opioid receptors, μ, δ, and κ, have been defined pharmacologically. Both spinal and vagal sensory neurons express different numbers of μ-, δ-, and κ-opioid receptors that are transported into the peripheral axons (1, 13, 15, 17, 31). The κ-opioid receptor (KOR) agonist fedotozine decreases sensitivity of rat visceral afferents to gastric and colonic distension (7). Despite robust effects of KOR ligands, μ- and δ-opioid receptor agonists have not been found to affect mechanosensitivity in these models (20, 34), indicating selectivity of expression within rodent distension-sensitive afferents. The effect of opioid agonists in other species and on different classes of visceral afferents is unknown: for instance mucosal mechanoreceptors, which only respond to mucosal stroking (22, 23). Such effects may have an important bearing on interpretation of clinical findings, such as the inhibitory effect of the μ-opioid receptor (MOR) agonist morphine on triggering of transient lower esophageal sphincter (LES) relaxation by gastric distension in humans (27) and the effect of opioids on the perception of mechanical events in the human gut (10).

We chose the ferret as our species for investigation because of a number of similarities with humans: the occurrence of vomiting and gastroesophageal reflux, the similarity of its upper gastrointestinal anatomy, and the fact that observations of pharmacology of ferret gastroesophageal vagal afferents in vitro translates to effects on mechanical triggering of transient LES relaxations and thus gastroesophageal reflux in humans (22, 23). Using this in vitro preparation, we investigated the effect of selective MOR, KOR, and δ-opioid receptor (DOR) agonists on the sensitivity of esophageal vagal afferents to mechanical stimulation. We studied all of the mechanosensitive esophageal vagal afferent subtypes to determine whether opioid actions are specific to a select sensory modality of vagal afferent fiber.

METHODS

All studies were approved and performed in accordance with the guidelines of the Animals Ethics Committees of the Royal Adelaide Hospital and the Institute for Medical and Veterinary Science, Adelaide, and also the Animal Ethics Committee of the University of Adelaide.

In vitro ferret gastroesophageal afferent preparation. This preparation has been described in detail previously (21, 22, 24, 25). Briefly, ferrets (0.6–1.0 kg body wt) were deeply anesthetized with sodium pentobarbitone (50 mg/kg ip) and exsanguinated by cardiac puncture. The stomach and esophagus with attached vagal nerves were dissected in a modified Krebs solution of the following composition (in mM): 118.1 NaCl, 4.7 KCl, 25.1 NaHCO3, 1.3 NaH2PO4, 1.2 mgSO4, 7H2O, 1.5 CaCl2, 1.0 citric acid, and 11.1 glucose, bubbled with 95% O2 and 5% CO2. The preparation was then opened longitudinally along the esophagus and pinned out flat, mucosal side up, in a Perspex chamber and perfused at a rate of 12 ml/min with Krebs bicarbonate buffer solution maintained at 34°C containing nifedipine (1 μM) to prevent smooth muscle contraction. The vagus nerve was drawn through a small hole into an isolated recording chamber filled with paraffin oil. Under a dissecting microscope, a small longitudinal incision was made in the nerve sheath. By use of fine forceps, nerve fibers were teased back onto a platinum recording electrode.

Characterization of esophageal vagal afferent properties. Location of receptive fields of all types of vagal afferent fibers was determined by mechanical stimulation throughout the preparation with a brush, then more accurately with a blunt glass rod. Accurate quantification of mechanical responsiveness was performed differently according to the
primary adequate stimulus for the type of fiber. Mechanical thresholds of all types were determined by using calibrated von Frey hairs. Mucosal receptors showed rapidly adapting responses to maintained pressure on the receptive field with a von Frey hair. This type of responsiveness was also seen in responses of tension/mucosal (TM) receptors to low-level mucosal mechanical stimulation. The most reproducible responses of these afferents to mucosal stimuli were evoked when the probe was moved at ~5 mm/s across the receptive field. Because receptive fields of these afferents are small (1–3 mm²), a single test at each intensity is likely to miss the center of the receptive field on occasions. Therefore, we minimized error by measuring the mean response to the middle 8 of 10 standard strokes given at 1-s intervals. Tension-response curves were also obtained for all afferent fibers, which were used in combination with von Frey thresholds to determine whether the receptive fields of fibers were located in the mucosa, the muscle layer, or both. Tension stimuli were applied via a thread attached to an unpinmed point adjacent to the mechanoreceptive field. The thread was attached to a cantilever system (22). Each weight was applied as a step and maintained for 1 min, and the response was measured as the mean discharge evoked over this period. Because all responses to tension were similarly slowly adapting, this method of assessment was considered representative of physiological responsiveness. The tension-response curves were produced by randomly applying weights to the cantilever system (1, 3, and 5 g). A recovery period of at least 1 min was allowed between each tension stimulus. Although conduction velocity was not recorded in this study, our previous observations indicate that these are in the C- and A-δ range, with no functional differences according to conduction velocity (21, 22).

Effect of opioid receptor agonists on the mechanosensitivity of vagal afferents. After mechanical sensitivity of the esophageal vagal afferent had been established, the effect of the MOR agonist [o-Ala²,N-Me-Ph⁴,Gly⁰]-enkephalin (DAMGO) on mechanical sensitivity was determined. DAMGO (0.1 M) was added to the superfusing solution and allowed to equilibrate for 20 min, after which the tension-response and stroke-response curves were redetermined. This equilibration period was observed so as to ensure penetration of the drug into all layers of the tissue. This procedure was repeated for DAMGO at increasingly higher doses (0.3–1 μM).

The same procedure was carried out for the KOR agonist 2-(3,4-dichlorophenyl)-N-methyl-N-[1(1S)-1phenyl-2-(1-pyrrolidinyl) ethyl] acetamide hydrochloride (IC 199441; 1–10 μM) and the DOR agonist (+)-4-[(aR)-α-(2S,5R)-4-allyl-2,5-dimethyl-1-piperazinyl]-3-methoxybenzyl]-N,N-dietlybenzamide (SNC-80; 0.01–1 mM) in different groups of experiments. Time control experiments were performed in which there was no significant change in the mechanical responses over a comparable duration.

Effect of opioid antagonism and agonism on the mechanical sensitivity of ferret mucosal afferents. After the mechanical sensitivity of the esophageal mucosal receptors had been established, the effect of the agonists DAMGO (1 μM) or ICI 199441 (10 μM) on mechanical sensitivity to mucosal stroking was determined in separate series of experiments. The maximal concentration of agonist was then added to the Krebs superfusing solution along with DAMGO (0.1 μM) or ICI 199441 (10 μM) and allowed to equilibrate for 20 min. Mechanical response relationships were then redetermined.

Data recording and analysis. Afferent impulses were amplified with a biological amplifier (DAM 50; World Precision Instruments, Sarasota, FL), filtered (band-pass filter-932; CWE, Ardmore, PA), and monitored by use of an oscilloscope (DL 1200 A; Yokogawa, Tokyo). Single units were discriminated on the basis of action potential shape, duration, and amplitude via Spike 2 software (Cambridge Electronic Design, Cambridge, UK). All data were recorded and analyzed offline with a personal computer (IBM Thinkpad). Peristimulus time histo-grams and discharge traces were displayed by using Spike 2 software.

Data are expressed as means ± SE, with n = number of individual afferents in all instances. Differences between stimulus-response curves were evaluated by two-way ANOVA. Differences were considered significant if P < 0.05.

Drugs. Stock solutions of all drugs were kept frozen and diluted to their final concentration in Krebs solution on the day of the experiment. DAMGO, ICI 199441, and SNC-80 were all obtained from Tocris Bioscience (Northpoint, Avonmouth, UK), and naloxone was obtained from Sigma (Castle Hill, NSW, Australia).

RESULTS

Mechanosensory properties of esophageal vagal afferent fibers. Three types of mechanosensitive fiber were observed using this in vitro preparation: those responding to circumferential tension but not low-intensity mucosal stimuli (tension receptors; n = 19), those responding only to mucosal stroking (mucosal receptors; n = 23), and those responding to both mucosal stroking and circumferential tension, which we have previously termed tension mucosal, or TM, receptors (n = 35) (22). All of the afferent fibers recorded had receptive fields in the esophagus or the gastroesophageal junction.

Effect of DAMGO on the mechanosensitivity of esophageal vagal afferents. The selective MOR agonist DAMGO (0.1–1 μM) (12, 16) did not significantly affect the basal discharge of vagal esophageal mucosal, tension, or TM receptors (data not illustrated). The effect of DAMGO on mucosal, tension, and TM receptor sensitivity to mechanical stimulation is illustrated in Fig. 1 and summarized in Table 1. A typical response of a tension receptor to circumferential tension (3 g) is illustrated in Fig. 1D. DAMGO (0.3–1 μM) significantly and dose dependently reduced the response of mucosal receptors to mucosal stroking with calibrated von Frey hairs (10–1,000 mg; Fig. 1A). DAMGO (0.1–1 μM) significantly and dose dependently reduced the response of tension receptors to circumferential tension (1, 3, and 5 g; Fig. 1, B and D). DAMGO (0.1–1 μM) did not significantly affect the response of TM receptors to either mucosal stroking with calibrated von Frey hairs (10–1,000 mg; Fig. 1Ci) or circumferential tension (1, 3, and 5 g; Fig. 1Cii).

Effect of ICI 199441 on the mechanosensitivity of esophageal vagal afferents. The selective KOR agonist ICI 199441 (1–10 μM) (3, 18) did not significantly affect the basal discharge of vagal esophageal mucosal, tension, or TM receptors (data not illustrated). The effect of ICI 199441 on mucosal, tension, and TM receptor sensitivity to mechanical stimulation is illustrated in Fig. 2 and summarized in Table 1. A typical response of a mucosal receptor to mucosal stroking with a 50 mg von Frey hair is illustrated in Fig. 2D. ICI 199441 (10 μM) significantly and dose dependently reduced the response of mucosal receptors to mucosal stroking with calibrated von Frey hairs (10–1,000 mg; Fig. 2, A and D). ICI 199441 (3–10 μM) significantly and dose dependently reduced the response of tension receptors to circumferential tension (3 and 5 g; Fig. 2B). ICI 199441 (3–10 μM) significantly and dose dependently reduced the response of TM receptors to mucosal stroking with calibrated von Frey hairs (10–1,000 mg; Fig. 2Ci) but did not significantly affect the response of the same TM receptors to circumferential tension (1, 3, and 5 g; Fig. 2Cii).
Effect of SNC-80 on the mechanosensitivity of esophageal vagal afferents. The selective DOR agonist SNC-80 (0.01–1 mM) (4, 30) did not significantly affect the basal discharge of vagal esophageal mucosal, tension, or TM receptors (data not illustrated). The effect of SNC-80 on mucosal, tension, and TM receptor sensitivity to mechanical stimulation is illustrated in Fig. 3 and summarized in Table 1. A typical response of a tension receptor to circumferential tension (3 g) is illustrated in Fig. 3D. SNC-80 (0.01–1 mM) only reduced the response of mucosal receptors to mucosal stroking with the 1,000 mg von Frey hair. SNC-80 (0.01–1 mM) did not significantly affect the response of tension receptors to circumferential tension (1, 3, and 5 g; Fig. 3D). SNC-80 (0.01–1 mM) did not significantly affect the response of TM receptors to either mucosal stroking with calibrated von Frey hairs (10–1,000 mg; Fig. 3C1i) or circumferential tension (1, 3, and 5 g; Fig. 3C1ii).

Effect of opioid receptor antagonism on the inhibitory effect of DAMGO and ICI 199441. The effect of the nonselective opioid receptor antagonist naloxone on inhibition of ferret esophageal mucosal receptors by opioid agonists is shown in Fig. 4. DAMGO (1 μM) alone significantly reduced the response of mucosal receptors (n = 6) to mucosal stroking with

calibrated von Frey hairs (10–1,000 mg; Fig. 4, A and C). When naloxone (10 μM) was added to the Krebs superfusate along with DAMGO (1 μM), the inhibitory effect of DAMGO was completely reversed to control values (Fig. 4A). A comparable reversal of the effect of ICI 199441 (10 μM) was seen with naloxone (10 μM, Fig. 4B).

**DISCUSSION**

The present study provides the first evidence that visceral afferents are differentially affected by opioid receptor agonists. Our results confirm previous reports that KOR agonists reduce the sensitivity of rat vagal tension receptors (20). We further demonstrate that the KOR agonist reduced the mechanosensitivity of mucosal receptors and TM receptor responses to mucosal stroking. This study provides the first evidence that activation of MORs inhibits visceral afferent mechanosensitivity, showing reduced sensitivity of a select population of esophageal vagal afferents by DAMGO. The MOR agonist reduced the sensitivity of mucosal and tension receptors but not the sensitivity of TM receptors. MOR effects were reversed by
the nonselective opioid antagonist naloxone. The DOR agonist SNC-80 had no substantial effect on any of the afferent types investigated in this study, indicating a lack of involvement of these receptors in esophageal vagal afferent function.

The effect of opioids are mediated by three distinct receptors: \( \kappa \), \( \mu \), and \( \delta \)-opioid receptors. The \( \mu \)- and \( \delta \)-opioid receptor gene expression has been observed in rat nodose ganglia with a relatively high expression of MOR RNA compared with other ganglia (6). There is also evidence of axonal transport of MOR along the vagus nerve both toward the brain and toward the periphery (15). This expression of the MOR in nodose ganglia and transport to the periphery correlates strongly with our findings that the \( \mu \)-receptor agonist DAMGO has an effect on the mechanosensitivity of mucosal and tension sensitive vagal afferent mechanoreceptors. However, it has been shown that morphine, the MOR agonist, has no effect on the response of rat gastric mechanoreceptors to gastric distension (20). What, then, is the function of MOR expressed in rat nodose ganglia? This discrepancy between studies may be a regional difference, because all afferents recorded in the present study were located in the esophagus or the LES and were therefore a totally different anatomical population than...
the gastric afferents previously reported (20). However, it should be noted that the esophageal tension receptors on which we observed effects of DAMGO are otherwise indistinguishable in their pharmacology from gastric tension receptors in ferret (21, 25, 26), suggesting a species variation.

Our data are in contrast to those obtained by Eastwood and Grundy (11), who showed direct excitation of rat small intestinal afferents by DAMGO in vivo. We would expect that the differences in findings are due to the release of other mediators by μ-opioids in the small intestinal mucosa, which has many cells that possess opioid receptors (14, 19). The esophagus, on the other hand, has a squamous epithelium with no enteroendocrine cell population, where opioid effects are more likely to be direct on the afferent ending, such as has been suggested from behavioral studies in skin (8, 37). In the skin, about one-third of unmyelinated cutaneous sensory axons are immuno-positive for MORs and DORs (8). In addition, morphine has been shown to reduce the response of cutaneous afferents to mechanical, thermal, and chemical activation (41, 42). Further down the intestine, μ-opioids do not affect the mechanically evoked discharge of afferent fibers innervating the rat colon (35, 38). However, it appears from less specific models of chemically evoked visceral pain that MOR analgesia may occur peripherally (9, 29). In our hands, the inhibitory effect of MOR agonists on mechanoreceptors is relatively selective for vagal esophageal mechanoreceptors, specifically mucosal receptors and tension receptors as opposed to TM receptors.

DOR expression in rat nodose ganglia is relatively low compared with other ganglia (6). In the present study, SNC-80, the DOR agonist, inhibited mucosal receptors only at the highest dose used and had no effect of the mechanosensitivity of tension receptors. This is in agreement with studies on
gastric vagal mechanoreceptors in the rat, which were also unaffected by SNC-80 (20). It may be that the DOR detected within rat nodose ganglia (6) are associated with neurons other than those innervating the gastroesophageal region.

Systemic administration of KOR agonists attenuates responses to noxious colorectal distension (5). In addition, it has been shown that KOR agonists, but not MOR or DOR agonists, inhibit responses of mechanosensitive pelvic nerve afferent fibers to noxious colorectal or urinary bladder distension in the rat in vivo (34, 35, 39, 40). In the rat stomach it has been shown that KOR agonists, but not MOR or DOR agonists, significantly affected the spontaneous activity of polymodal nociceptors in rat paw skin induced by ultraviolet irradiation.
