Zimmerman MA, Singh N, Martin PM, Thangaraju M, Ganapathy V, Waller JL, Shi H, Robertson KD, Munn DH, Liu K. Butyrate suppresses colonic inflammation through HDAC1-dependent Fas upregulation and Fas-mediated apoptosis of T cells. *Am J Physiol Gastrointest Liver Physiol* 302: G1405–G1415, 2012. First published April 19, 2012; doi:10.1152/ajpgi.00543.2011. —Butyrate, an intestinal microbiota metabolite of dietary fiber, has been shown to exhibit protective effects toward inflammatory diseases such as ulcerative colitis (UC) and inflammation-mediated colorectal cancer. Recent studies have shown that chronic IFN-γ signaling plays an essential role in inflammation-mediated colorectal cancer development in vivo, whereas genome-wide association studies have linked human UC risk loci to IFNG, the gene that encodes IFN-γ. However, the molecular mechanisms underlying the butyrate-IFN-γ-colonic inflammation axis are not well defined. Here we showed that colonic mucosa from patients with UC exhibited increased signal transducer and activator of transcription 1 (STAT1) activation, and this STAT1 hyperactivation is correlated with increased T cell infiltration. Butyrate treatment-induced apoptosis of wild-type T cells but not Fas-deficient (Fas0/−) or FasL-deficient (Fas0/−/FasL−/−) T cells, revealing a potential role of Fas-mediated apoptosis of T cells as a mechanism of butyrate function. Histone deacetylase 1 (HDAC1) was found to bind to the Fas promoter in T cells, and butyrate inhibits HDAC1 activity to induce Fas promoter hyperacetylation and Fas upregulation in T cells. Knocking down gpr109a or slc5a8, the genes that encode for receptor and transporter of butyrate, respectively, resulted in altered expression of genes related to multiple inflammatory signaling pathways, including inducible nitric oxide synthase (iNOS), in mouse colonic epithelial cells in vivo. Butyrate effectively inhibited IFN-γ-induced STAT1 activation, resulting in inhibition of iNOS upregulation in human colon epithelial and carcinoma cells in vitro. Our data thus suggest that butyrate delivers a double-hit: induction of T cell apoptosis to eliminate the source of inflammation and suppression of IFN-γ-mediated inflammation in colonic epithelial cells, to suppress colonic inflammation.

Fas promoter; histone deacetylase 1

**COMPELLING DATA FROM BOTH** human patients and animal model-based studies have shown that aberrant host immune response triggered by intestinal microbiota is a requisite for the onset of inflammatory diseases such as ulcerative colitis (UC) and colitis-associated colorectal cancer (15, 18, 47, 49). Although the etiology of UC is still not clear and the role of the proinflammatory cytokine IFN-γ in UC is controversial, recent Meta analysis and genome-wide association studies of large cohorts of human patients have surprisingly identified IFNG, the gene encoding for IFN-γ, as a UC susceptibility locus in humans (1, 30, 39).

IFN-γ is a proinflammatory cytokine that exerts its inflammatory function through signal transducer and activator of transcription 1 (STAT1) to regulate the expression of inflammatory mediators such as inducible nitric oxide synthase (iNOS) and cyclooxygenase 2 (COX2) in the colonic tissues (18). It has been reported that IFN-γ secretion is elevated in the peripheral blood (16) and IFN-γ expression level is increased in the inflamed colonic mucosa tissues in patients with UC (46). The expression and activation level of STAT1 is also significantly increased in colonic tissues of patients with UC (37). These observations thus suggest that IFN-γ might play a key role in human UC pathogenesis (16, 46) and inflammation-dependent spontaneous colorectal cancer development (2, 18).

IFN-γ is secreted by activated T cells. Therefore, infiltration and persistence of activated T cells in the colonic tissues might be the source of IFN-γ and thereby a cause of colonic inflammation. Indeed, whereas IL-10 knockout (IL10−/−) mouse exhibits intolerance to intestinal microbiota and goes on to develop spontaneous colitis, IL10−/− Rag2−/− mouse fails to develop colitis, suggesting that UC is a T cell-mediated inflammatory disorder (27, 47).

A promising class of agents with both preventive and therapeutic potential to counteract inflammation-mediated UC and colorectal cancer is short-chain fatty acids, most notably butyrate (10, 22, 43). Butyrate is a major metabolite in colonic lumen arising from bacterial fermentation of dietary fiber and has been shown to be a critical mediator of the colonic inflammatory response (10, 21–22, 24, 40). One mechanism underlying butyrate function in suppression of colonic inflammation is inhibition of the IFN-γ/STAT1 signaling pathways (23, 40). Butyrate may exert its anti-inflammatory function through acting as a histone deacetylase (HDAC) inhibitor (10–11, 48); however, the specific molecular targets of butyrate as a HDAC inhibitor and molecular mechanisms of inhibition are not well-defined.

We conducted an in-depth analysis of butyrate function in both T cells and colonic epithelial cells and determined that butyrate delivers a double-hit to inhibit inflammation: first, butyrate inhibits IFN-γ-induced STAT1 activation and iNOS upregulation to suppress inflammation in colonic epithelial and carcinoma cells; second and more importantly, butyrate inhibits Fas promoter-bound HDAC1 activity to induce Fas promoter hyperacetylation and Fas upregulation to enhance Fas-mediated apoptosis of T cells, resulting in termination of the uncontrolled T cell activation, thereby, eliminating the source of inflammation in the colonic tissue.
MATERIALS AND METHODS

Mice and cells. BALB/c (H-2b) mice were obtained from the National Cancer Institute (NCI, Frederick, MD). C57BL/6J, Fas-deficient (Fas<sup>−/−</sup>), and FasL-deficient (FasL<sup>−/−</sup>) mice were obtained from the Jackson Laboratory (Bar Harbor, ME). slc5a8<sup>−/−</sup> and gpr109a<sup>−/−</sup> mice were originally obtained from Dr. Thomas Boettger (Max-Planck-Institut für Herz, Lundgenforschung, Germany) and Dr. Stefan Offermanns (University of Heidelberg, Heidelberg, Germany), respectively. All mice were housed, maintained, and studied in accordance with approved NIH and Georgia Health Sciences University guidelines for animal use and handling. C57B/6J and Fas<sup>−/−</sup> mice were obtained from ATCC (Manassas, VA). All cells were maintained in RPMI 1640 (Biolegend) containing 10% FCS (Atlanta, GA) and antibiotics. They are adherent epithelial cells obtained from ATCC (Manassas, VA). CCD-841 and T84 cells were obtained from American Type Culture Collection (ATCC) (Manassas, VA). ATCC characterizes these cells by morphology, immunology, DNA fingerprint, and cytogentic.

Immunohistochemistry. The human colorectal cancer progression tissue microarray (TMA) was obtained from the Cooperative Human Tissue Network. Immunohistochemical staining was carried out by the Georgia Pathology Service. CD3 antibody was obtained from Dako (Carpinteria, CA). STAT1 antibody was obtained from BD Biosciences (San Jose, CA).

Analysis of T cell activation. Twenty-four-well plates were coated with anti-CD3 (clone 145-2C11; Biolegend, San Diego, CA) and anti-CD28 (clone: 28.2, Biolegend) mAbs. Spleen cells (1 × 10<sup>6</sup> cells/well) were then seeded in the mAb-coated plates. Cells were collected and stained with PE-conjugated anti-CD4, APC-conjugated CD25, and FITC-conjugated CD69 mAbs (Biolegend) at 4°C for 20 min. Cells were washed twice with PBS and then incubated with anti-mouse IgG-conjugated and anti-Rat IgG-conjugated magnetic beads (Polysciences, Warrington, PA). The bound cells were removed by a magnetic stand. Proliferation assay was performed using the MTT proliferation kit (ATCC) according to manufacturer’s instructions.

Cell proliferation assay. To purify CD<sup>+</sup> or CD<sup>+</sup> T cells, spleen cells were incubated with anti-CD19, CD4 (for CD<sup>+</sup> T cell purification), CD8 (for CD<sup>+</sup> T cell purification), CD11b, and NK mAbs (all from Biolegend) at 4°C for 20 min. Cells were washed twice with PBS and then incubated with anti-mouse IgG-conjugated and anti-Rat IgG-conjugated magnetic beads (Polysciences, Warrington, PA). The bound cells were removed by a magnetic stand. Proliferation assay was carried out essentially as previously described (50). The blot was probed with anti-pSTAT1 antibody (BD Biosciences), followed by reprobing with anti-β-actin antibody (Sigma, St. Louis, MO).

Western blot analysis. Western blotting analysis was performed essentially as previously described (50). The blot was probed with anti-pSTAT1 antibody (BD Biosciences), followed by reprobing with anti-β-actin antibody (Sigma, St. Louis, MO).

RESULTS

STAT1 hyperactivation is linked to T cell accumulation in colonic tissues in UC. A TMA slide containing normal colon tissue from patients with colorectal cancer and colon tissues from patients with UC was stained for CD3 and STAT1 protein levels. As expected, CD3<sup>+</sup> T cells were present in the mucosa (Fig. 1A, a1 and a2). However, five of the six UC colon tissue specimens showed greater T cell infiltration than the normal colon tissue (Fig. 1A, b1 and b2). Statistical analysis determined that the UC colon tissues have a significantly higher mean number of T cells than the normal colon tissue group (Fig. 1C). Less than 10% of normal colonic epithelial cells expressed detectable cytoplasmic STAT1 (cSTAT1), and a slightly higher percentage of them expressed nuclear STAT1 (nSTAT1) (Fig. 1B). Mucosal tissues from patients with UC exhibited higher percentages of both cSTAT1 and nSTAT1 than the normal mucosal tissues (Fig. 1B), and the differences were statistically significant (Fig. 1C). The intensity of nSTAT1 in mucosal epithelial cells from patients with UC is also significantly higher than that of normal mucosal epithelial cells (data not shown). Spearman rank correlation analysis revealed a statistically significant moderate and positive correlation between number of CD3<sup>+</sup> T cells and the percentages of both cSTAT1- and nSTAT1-positive colonic epithelial cells (data not shown). These observations thus indicate that activation of the IFN-γ signaling pathway in the colonic mucosa is linked to accumulation of T cells in human patients with UC.

Butyrate inhibits T cells activation. To determine the T cell activation kinetics, total mouse spleen cells were cultured in anti-CD3 and anti-CD28 mAb-coated plates. Cells were then collected overtime and stained for cell surface CD4, CD69, and CD25. CD25<sup>+</sup> cells were then gated and analyzed for CD25 and CD69 mean fluorescence intensity and percentage of positive cells. Analysis of CD69<sup>+</sup> and CD25<sup>+</sup> cells among the CD4<sup>+</sup> cell population indicated that T cell activation plateau at ~24 h, with more than 70% of T cells being activated (Fig. 2A).

Next, spleen cells were stimulated with anti-CD3 and anti-CD28 mAbs in the presence of butyrate for 24 h and examined for CD4<sup>+</sup> T cell activation. Butyrate at concentrations up to 3 mM did not inhibit the early activation marker CD69 expression intensity on CD4<sup>+</sup> T cells nor the percentage of CD69<sup>+</sup> CD4<sup>+</sup> T cells (Fig. 2B). However, higher concentrations of butyrate (5 mM) did decrease CD69 level (Fig. 2B).
inhibited by butyrate in a dose-dependent manner (Fig. 2B). Taken together, our data suggest that butyrate partially inhibits CD4+ T cell activation.

Butyrate inhibits T cell proliferation. To determine whether the above-observed partial inhibition of T cell activation by butyrate is accompanied by inhibition of T cell proliferation, we purified both CD4+ and CD8+ T cells. The purified T cells were activated with anti-CD3/CD28 mAbs for 3 days in the presence of various concentrations of butyrate and analyzed for proliferation by MTT assay. Low concentrations of butyrate (<1 mM) did not exhibit a significant inhibitory effect on CD4+ T cells, but high concentrations of butyrate (>3 mM) significantly inhibited proliferation of both CD4+ and CD8+ T cells in vitro (Fig. 3, A and B).

Butyrate enhances activation-induced cell death of T cells. To determine whether the above-observed inhibition of proliferation is due to increased cell death, we activated T cells in the presence of butyrate and analyzed T cell apoptosis. Flow cytometry analysis indicated that butyrate increased apoptosis of resting CD4+ T cells (Fig. 3C) and CD8+ T cells (Fig. 3D) in a dose-dependent manner. Butyrate also significantly increased apoptosis of activated CD4+ T cells (Fig. 3C) and CD8+ T cells (Fig. 3D) in a dose-dependent manner. In summary, our data suggest that butyrate is a potent apoptosis inducer of CD4+ and CD8+ T cells.

Induction of apoptosis by butyrate in T cells is Fas-dependent. Termination of an immune response after clearance of pathogen-infected or diseased cells is primarily through elimination of effector T cells through Fas-FasL interaction to induce Fas-mediated apoptosis under physiological conditions (25). To determine whether butyrate-induced apoptosis is Fas-dependent, we examined the effects of butyrate on T cells isolated from FasL-deficient (Fas−/−) and Fas-deficient (Fas−/−) mice. As observed above, butyrate enhanced wild-type (WT) CD4+ and CD8+ T cell apoptosis (Fig. 4A). However, CD4+ and CD8+ T cells derived from Fas−/− and Fas−/− mice were resistant to butyrate-induced apoptosis (Fig. 4A). Our results thus indicate that butyrate induces apoptosis in T cells through the Fas-mediated apoptosis pathway.
Butyrate inhibits HDAC1 activity to induce Fas promoter hyperacetylation and Fas upregulation. To determine the effects of butyrate on Fas expression in T cells, spleen cells were stimulated with anti-CD3/CD28 mAbs in the presence of butyrate. Fas protein levels on CD4\H11001 and CD8\H11001 T cell surfaces were analyzed by flow cytometry. Low doses of butyrate significantly increased Fas protein levels in both CD4\H11001 and CD8\H11001 T cells. High-dose (3 mM) butyrate, however, exhibited minimal effects on Fas protein level (Fig. 4B), possibly attributable to protein degradation in the dying cells (Fig. 3).

To determine whether Fas expression is regulated by histone acetylation, we examined the association of HDACs with the Fas promoter region in T cells. Mouse T cells were stimulated with anti-CD3/CD28 antibody-conjugated magnetic beads and subjected to ChIP using HDAC1- and HDAC2-specific antibodies. PCR amplification of the immunoprecipitated genomic DNA revealed that HDAC1 but not HDAC2 is physically associated with the Fas promoter region in the activated T cells in the absence and presence of butyrate (Fig. 4C). In vitro assays with purified HDAC1 indicated that butyrate inhibits HDAC1 activity (Fig. 4D). Next, we sought to determine whether butyrate-mediated inhibition of HDAC1 leads to an increase in Fas promoter histone acetylation. ChIP assay using an acetyl-H3-Lys9-specific antibody revealed that butyrate induces hyperacetylation of H3 in the Fas promoter region (Fig. 4C). Taken together, our data suggest that butyrate inhibits the Fas promoter-bound HDAC1 activity to hyperacetylate the Fas promoter, consequently resulting in the upregulation of Fas expression in T cells.

Butyrate transporter and receptor expression and function. Butyrate can enter mammalian cells through the Na\H11001-coupled transporter, slc5a8, via a Na\H11001-dependent electrogenic process (31). However, the expression of slc5a8 is often silenced in colon cancer cells (26). Butyrate can also elicit its biological effects on colonic epithelial cells without transportation into cells, via the G protein-coupled butyrate receptor, gpr109a (44). To determine whether butyrate exerts its apoptosis-inducing function through the transporter, slc5a8, or the receptor, gpr109a, we examined the expression and functions of slc5a8 and gpr109a in T cells. The −3,000 to +1,000 region of the
mouse slc5a8 promoter region contains two typical CpG islands (Fig. 5A), whereas, that same region of the gpr109a promoter contains a nontypical (>60% GC content) CpG island (Fig. 5A). DNA sequence analysis of the bisulfite-modified genomic DNA isolated from mouse CD4+ and CD8+ T cells revealed that the slc5a8 promoter region is only sporadically methylated in CD4+ and CD8+ T cells, whereas the gpr109a promoter region is heavily methylated in both CD4+ and CD8+ T cells (Fig. 5B). However, despite the fact that the slc5a8 promoter is partially methylated and the gpr109a promoter is heavily methylated, RT-PCR analysis indicated that both slc5a8 and gpr109a are expressed in T cells, albeit at low level (Fig. 5C).

To determine whether slc5a8 or gpr109a mediates butyrate function in T cells, we stimulated T cells derived from WT, slc5a8-null (slc5a8−/−), and gpr109a-null (gpr109a−/−) mice with anti-CD3/CD28 mAbs in the absence and presence of butyrate and analyzed T cell apoptosis. We observed that CD4+ and CD8+ T cells isolated from slc5a8−/− and gpr109a−/− mice were still sensitive to butyrate-induced apoptosis (Fig. 5D), suggesting that GPR109A and SLC5A8 might compensate for each other’s functions in T cells.

GPR109A and SLC5A8 mediate expression of inflammation-related genes in colonic tissue. The above observations suggest that SLC5A8 and GPR109A might compensate for butyrate function in T cells. Because butyrate functions to inhibit colonic inflammation, we reasoned that deletion of slc5a8 or gpr109a alters the expression of inflammation-related genes in the colonic mucosa. Therefore, we collected colon mucosal tissues from conventional WT, slc5a8−/−, and gpr109a−/−
mice and analyzed the expression levels of sets of genes with known functions in colonic inflammation. RT-PCR analysis revealed that iNOS, a marker of inflammation, is dramatically upregulated in colonic mucosa from slc5a8/H11002 mice. The expression levels of several genes of the IFN-γ and TGF-β signaling pathways, namely STAT1, STAT2, IFN regulatory factor (IRF)4, IRF5, suppressor of cytokine signaling (SOCS)1, and SMAD6, are upregulated in the colonic mucosa from slc5a8/H11002 mice (Fig. 6). STAT4, IRF4, IRF5, SMAD6, and SMAD7 are upregulated in the colonic mucosa from gpr109a/H11002 mice (Fig. 6). Taken together, these observations suggest that slc5a8 and gpr109a mediate expression of distinct genes that are involved in inflammatory response in colonic epithelial cells in vivo.

Butyrate inhibits IFN-γ signaling but not proliferation in human colonic epithelial cells. To functionally determine whether butyrate mediates inflammatory response in colonic epithelial cells, we examined the effects of butyrate on proliferation, Fas expression, and IFN-γ signaling in the normal human colonic epithelial cell line CCD-841 in vitro. Flow cytometry analysis of cell surface Fas protein level indicated that exposure to butyrate resulted in no significant alteration in Fas receptor level. MTT assay revealed that, in contrast to what was observed in T cells, butyrate did not inhibit CCD-841 cell proliferation at a concentration as high as 10 mM (data not shown). IFN-γR is expressed on CCD841 cells (Fig. 7A). IFN-γ treatment in vitro induced STAT1 phosphorylation (pSTAT1), and butyrate inhibited this IFN-γ-induced STAT1 activation (Fig. 7B). Because iNOS is not expressed in CCD-841 cells and IFN-γ plus LPS did not induce iNOS expression in CCD-841 cells, we used colon carcinoma cell line T84 to determine the effects of butyrate on iNOS induction. IFN-γ and LPS induced a high level of iNOS expression, and butyrate effectively inhibited iNOS induction (Fig. 7C). Taken together, our data suggest that butyrate suppresses colonic inflammation at least in part through inhibiting iNOS upregulation in human colonic epithelial cells.
DISCUSSION

Multiple recent Meta analysis and genome-wide association studies of large cohorts of human patients have linked IFNG, the gene encoding for the proinflammatory cytokine IFN-γ, to human UC susceptibility (1, 30, 39). These findings firmly established a role of IFN-γ in the promotion of UC in humans. These data are consistent with several previous observations that increased mucosal expression of the IFN-γ gene, elevated secretion of IFN-γ protein, and increased levels of STAT1 expression and activation are associated with UC pathogenesis in human patients with UC (16, 37, 46). It has also been shown that treatment of mice with TNBS-induced colitis with IFN-γ neutralizing antibody can at least partially achieve reversal of colitis-associated weight loss (14). However, other studies indicated that IFN-γ signaling is not activated in colonic tissues of patients with UC (32). Furthermore, IFN-γ signaling might play a suppressive role against colonic inflammation and UC in an experimental colitis mouse model (32, 38). These contrasting observations might be due to the different experimental systems used in these studies. It is well-known that the host gut microbiota and immune cells are critical players in UC pathogenesis. The different composition of host gut microbiota may lead to different immune responses in different experimental systems or human patients, thereby resulting in different immune cell and cytokine profiles in the gut. In addition, it is known that acute IFN-γ signaling facilitates the clearance of infection and pathogens (13), whereas chronic IFN-γ signaling mediates chronic inflammation and inflammation-associated diseases, including UC and colorectal cancer (18, 37). Therefore, it is very likely that acute IFN-γ production may suppress UC (38), whereas it is the sustained/chronic T cell activation that causes sustained IFN-γ signaling, leading to IFN-γ-dependent and inflammation-mediated diseases.

IFN-γ is produced primarily by activated T cells and NK cells. Therefore, the increase in IFN-γ/pSTAT1 is most likely due to the increase in infiltrating T cells in the colonic mucosa (20). Our results indicate that colonic mucosa from patients with UC harbor significantly more T cells than the normal...
colonic tissues. This observation is consistent with human clinical data and animal-based studies that show a critical role of T cells in UC pathogenesis (6 –7, 35, 49). Therefore, it is very likely that one of the mechanisms underlying UC pathogenesis is persistence and accumulation of activated T cells in the colonic mucosa that leads to overproduction of IFN-γ. Overproduction of IFN-γ leads to sustained IFN-γ signaling and STAT1 hyperactivation. IFN-γ-induced STAT1 activation is usually transient under normal physiological conditions. In contrast, overexpressed IFN-γ-induced STAT1 hyperactivation may result in altered expression patterns of IFN-γ-regulated genes such as iNOS that promotes chronic inflammation in the colonic mucosa to promote UC and colorectal cancer (18).

Butyrate is primarily derived from dietary fiber by anaerobic bacterial fermentation in the colon and exhibits potent anti-inflammatory activity (11, 48). In this study, we carried out a proof-of-concept study with mouse T cells and observed that butyrate enhances T cell apoptosis. T cells are typically activated in response to normal stimuli followed by elimination after clearance of the antigen. This is crucial for avoiding autoimmunity and uncontrolled immune responses. Because of the persistent exposure to a diverse number of antigens encountered in the gastrointestinal tract, gut lamina propria T lymphocyte (T-LPL) numbers are controlled by induction of Fas-mediated apoptosis (12). T-LPL often express high levels of Fas (12, 19); however, in cases of inflammatory bowel disease, Fas expression levels in T-LPL as well as T-LPL sensitivity to Fas-mediated apoptosis are often decreased (3, 5, 41, 42). In the functional level, it was reported that mice with Fas deficiency in the colon tissues are hypersensitive to DSS-induced colitis (34), whereas mice lacking FasL exhibited more severe and persistent colitis than control WT mice (36). Furthermore, treatment with anti-IL-12 mAb resulted in increased Fas-mediated apoptosis of T cells and reversal of colitis (14). These studies thus indicate that the Fas-mediated apoptosis pathway in both colonic epithelial cells and T cells plays a critical role in prevention of colitis in mouse models in vivo. Therefore, one mechanism underlying colitis pathogenesis might be increased resistance to Fas-mediated apoptosis in both colonic epithelial cells and T cells. Thus butyrate may function to inhibit colonic inflammation through increasing T cell sensitivity to apoptosis to eliminate the source of inflammation. Butyrate functioning as an apoptosis promoter has been reported in tumor cells. Several studies have shown that butyrate either directly induces solid tumor cell apoptosis through its transporter slc5a8 and receptor gpr109a (44 – 45) or through sensitizing the tumor cells to Fas-mediated apoptosis.
Our results thus extend the function of butyrate in apoptosis induction from tumor cells to T cells. Butyrate elicits its apoptosis-inducing activity through its transporter SLC5A8 and receptor GPR109A in colon carcinoma cells (9, 31, 44 – 45). However, whereas knocking down either slc5a8 or gpr109a leads to altered expression of several inflammation-related genes in the colonic tissues, neither SLC5A8 nor GPR109A is essential for butyrate-mediated apoptosis in T cells, suggesting that the underlying molecular mechanisms of butyrate function in T cells might be different from that in colon epithelial cells, and that SLC5A8 and GPR109A might compensate for each other in T cells. However, it should be noted that, in addition to GPR109A and SLC5A8, butyrate also has other transporters and receptors, including monocarboxylate transporter 1, GPR41, and GPR43 (4, 17, 28). Nevertheless, SLC5A8 and GPR109A mediate...
expression of distinct genes, including iNOS, in the colonic epithelial cells in vivo. These genes are known to play key roles in inflammation in vivo (Fig. 6).

We observed that butyrate directly inhibits HDAC1 enzymatic activity. We also demonstrated that HDAC1 is bound to the Fas promoter in T cells. Therefore, it is reasonable to assume that hyperacetylation of the Fas promoter is a consequence of butyrate-mediated inhibition of HDAC1 activity at the Fas promoter region. Hyperacetylation leads to Fas receptor upregulation and consequently increased sensitivity of T cells to activation-induced cell death. Our results thus identify HDAC1 as a molecular target of butyrate and demonstrate that butyrate regulates the death receptor Fas expression to regulate T cell apoptosis.

Although the end effects of butyrate are readily observable, questions still remain, however, on how exactly butyrate is utilized by the cell, the role of the SLC5a8 transporter and the manner in which butyrate interacts with HDAC1. Our data suggest that butyrate has beneficial effects on two fronts: eliminating the source of inflammation by increasing Fas-mediated apoptosis of T cells and reducing the expression of proinflammatory transcription factor, STAT1, in colonic epithelial cells. Based on these findings, we propose a model to illustrate the preventive and therapeutic roles of butyrate in UC. We propose that butyrate delivers a double-hit to suppress colonic inflammation: first, butyrate inhibits STAT1 hyperactivation in colonic epithelial cells to inhibit IFN-γ-mediated chronic inflammation; second, butyrate inhibits Fas promoter-bound HDAC1 activity to induce Fas promoter hyperacetylation and Fas upregulation, resulting in enhanced apoptosis of T cells and thus decreased accumulation of T cells in the inflamed colonic mucosa (Fig. 8). Therefore, targeting the butyrate-HDAC1-Fas axis may offer an effective novel approach to eliminate the overreactive T mucosa (Fig. 8). Therefore, targeting the butyrate-HDAC1-Fas axis and thus decreased accumulation of T cells to activation-induced cell death. Our results thus identify HDAC1 as a molecular target of butyrate and demonstrate that butyrate regulates the death receptor Fas expression to regulate T cell apoptosis.

ACKNOWLEDGMENTS

We thank Ms. Kimberly Smith in the Georgia Pathology Services for the excellent technical assistance in the immunohistochemical staining of tissues. We also thank Dr. Jeanene Pihkala for assistance in flow cytometry analysis.
